

SMB enumeration is a very important skill for any pentester. Before learning how to enumerate SMB , we must first learn what SMB is . So let's get started.

SMB stands for server message block. It's a protocol for sharing resources like files, printers, in general any resource which should be retrievable or made available by the server. It primarily runs on port 445 or port 139 depending on the server . It is actually natively available in windows, so windows users don't need to configure anything extra as such besides basic setting up. In linux however ,it is a little different. To make it work for linux, you need to install a samba server because linux natively does not use SMB protocol.

Obviously some sort of authentication will be in place like a username and password and only certain resources made shareable. So it's not like everyone can access everything, a strong authentication.

So lets talk about the security flaws in this. The first obvious flaw is using default credentials or easily guessable and sometimes even no authentication for access of important resources of the server. Admins should make sure to use strong passwords for users who want to access resources using SMB.

The second flaw is the samba server. Samba servers are notorious for being tremendously insecure . Don't believe me? Just type in google "samba server exploit" and you'll get a list of publicly available exploits quite easily. Hell, even metasploit houses so many auxillary scanners and exploits for samba server. So make sure the Samba server is patched.

Ok ,so how do we enumerate when we find that in our nmap scan port 445 is open with samba server on. I only said samba server because linux is predominantly used by enterprises , around 75% to be precise. That being said, the process of enumeration for SMB is the same for both linux and windows with the exception that in linux , you have to check the samba version as well and check if it is vulnerable or not.

So what I like to do the first thing is use Nmap scripting engine or commonly known as NSE. It is a very powerful feature of Nmap and would probably require a separate article to demonstrate it's usefulness . So to enumerate version, type

```
nmap -p445 -- script smb-protocols <target ip>
```

```
nmap -p139 -- script smb-protocols <target ip>
```

Note we are trying to enumerate both port numbers . We could also try to enumerate smb using default scripts of the NSE by typing:

```
nmap -sC -p 139,445 -sV 10.0.2.30
```

These are the results when I ran it against a metasploitable

```

root@kali:~# nmap -sC -p 139,445 -sV 10.0.2.30
Starting Nmap 7.70 ( https://nmap.org ) at 2019-07-15 18:13 BST
Nmap scan report for 10.0.2.30
Host is up (0.00039s latency).

PORT      STATE SERVICE      VERSION
139/tcp    open  netbios-ssn  Samba smbd 3.X - 4.X (workgroup: WORKGROUP)
445/tcp    open  netbios-ssn  Samba smbd 3.0.20-Debian (workgroup: WORKGROUP)

Nmap done: 1 IP address (1 host up) scanned in 12.30 seconds
Default scriptscan for nmap

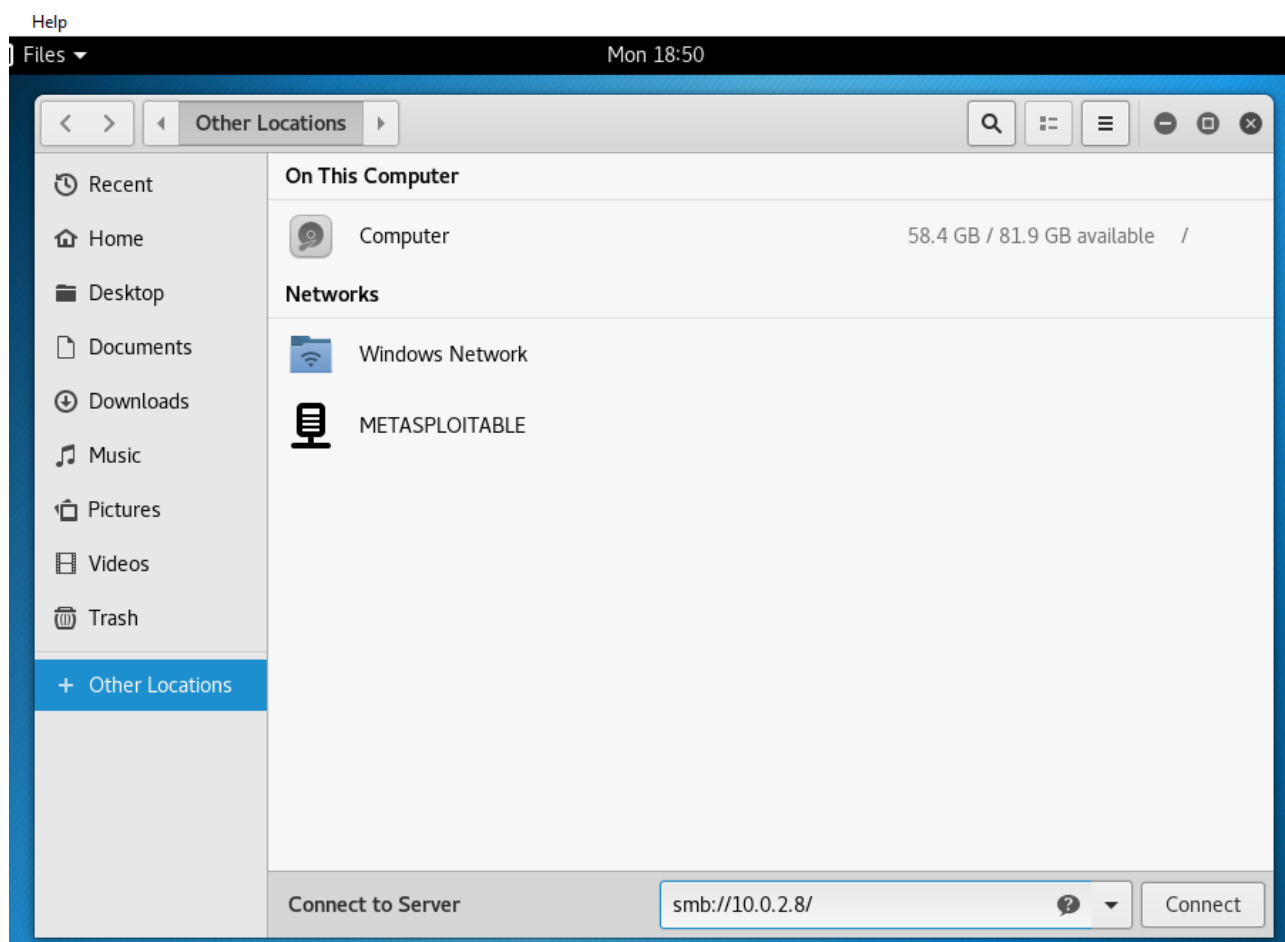

```

Nice ! we found out the version of Samba running in the server. Now just go to google and search whether the given version is vulnerable or not.

That's great , but what if the samba server was patched, or didn't have a samba server to begin with?

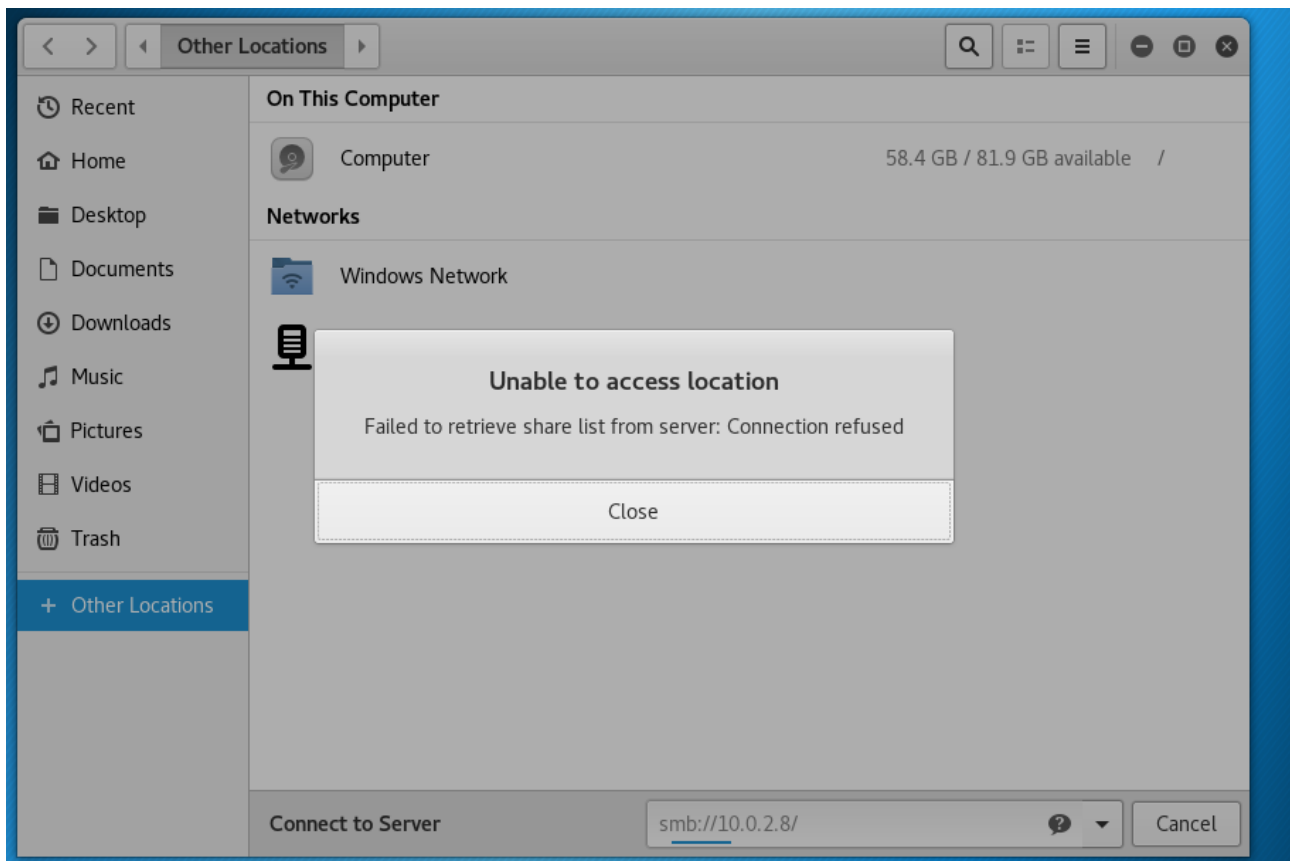

There are many ways to enumerate the service itself. The quickest way is to use a tool called enum4linux. However I have noticed that sometimes the output is not very pleasing. Other tools which I feel better are smbclient and smbmap. I will also show how to manually access smb folder , but sometimes that fails. So primarily , you should be well versed with smbclient and smbmap , they are much more reliable.

As promised , let us first access it manually. To manually access the smb shares, go to folders and type this:

You can connect like this also

Unfortunately, it fails

In few machines this fails

I am actually not sure why. It does work on a lot of machines, not sure why it's not working here. Anyway, this kind of makes my point why smbclient and smbmap are better.

Let's first use smbmap. To use its basic version, type

```

root@kali:~# smbmap -H 10.0.2.30
[+] Finding open SMB ports...
[+] User SMB session established on 10.0.2.30...
[+] IP: 10.0.2.30:445   Name: 10.0.2.30
Disk                                     Permissions
----                                     -
print$                                  NO ACCESS
tmp                                     READ, WRITE
opt                                     NO ACCESS
IPC$                                    NO ACCESS
ADMIN$                                  NO ACCESS

root@kali:~# smbmap -H 10.0.2.30 -R
[+] Finding open SMB ports...
[+] User SMB session established on 10.0.2.30...
[+] IP: 10.0.2.30:445   Name: 10.0.2.30
Disk                                     Permissions
----                                     -
print$                                  NO ACCESS
tmp                                     READ, WRITE
.\
dr--r--r--          0 Mon Jul 15 18:54:04 2019  .
dw--w--w--          0 Sun May 20 19:36:11 2012  ..
dr--r--r--          0 Mon Jul 15 17:48:19 2019  .ICE-unix

dr--r--r--          0 Mon Jul 15 17:49:09 2019  .X11-unix
-w--w--w--        11 Mon Jul 15 17:49:09 2019  .X0-lock
.\.X11-unix\
dr--r--r--          0 Mon Jul 15 17:49:09 2019  .
dr--r--r--          0 Mon Jul 15 18:54:04 2019  ..
-r--r--r--          0 Mon Jul 15 17:49:09 2019  X0
opt                                     NO ACCESS
IPC$                                    NO ACCESS
ADMIN$                                  NO ACCESS

```

The -H argument is for hostname and the -R is recursive switch, meaning it will go through each directory and list out the files. Although I must tell you that it's working now only because anonymous login is allowed, i.e. in a real life , you'd probably need a username and password.

Now you can actually retrieve the files using smbmap as well, I'll leave that as an exercise. But what if we wanted a full fledged command prompt like a ftp prompt? That's very much possible with smbclient. Lets try to do that.

```
root@kali:~# smbclient -N -L \\\10.0.2.30
WARNING: The "syslog" option is deprecated
Anonymous login successful

-----
Workgroup       Master
WORKGROUP      METASPLOITABLE
root@kali:~#
```

A smbclient connection is made to enumerate information

This command tries to establish an anonymous login with metasploitable so that we can see what all files we can access. You can see that it was successful and we have access to shares namely opt and tmp.

Now how do I get a smbshell in either of the disks? Simple, just type like this

```
root@kali:~# smbclient \\\10.0.2.30\\tmp
WARNING: The "syslog" option is deprecated
Enter WORKGROUP\root's password:
Anonymous login successful
Try "help" to get a list of possible commands.
smb: \> ls

```

As promised a smb interactive shell

Yay , we got a shell in tmp disk. Now we can download or upload files into the share. As you can see , this is actually useful for both system administrators and pentesters. That's why, the best way to start your ethical hacking career is to first be a system or network admin. It becomes easier down the lane if you start from there.

Hope it helped out some of the folks! Also , smb knowledge is must for enumerating oscp level machines. Thanks y'all
